# Chapter 2: Relational Model

- Structure of Relational Databases
- Fundamental Relational-Algebra-Operations
- Additional Relational-Algebra-Operations
- Extended Relational-Algebra-Operations
- Null Values
- Modification of the Database

# Example of a Relation

| <i>account_number</i> | <i>branch_name</i> | <i>balance</i> |
|-----------------------|--------------------|----------------|
| A-101                 | Downtown           | 500            |
| A-102                 | Perryridge         | 400            |
| A-201                 | Brighton           | 900            |
| A-215                 | Mianus             | 700            |
| A-217                 | Brighton           | 750            |
| A-222                 | Redwood            | 700            |
| A-305                 | Round Hill         | 350            |

# Attribute Types

- Each attribute of a relation has a name
- The set of allowed values for each attribute is called the **domain** of the attribute
- Attribute values are (normally) required to be **atomic**; that is, indivisible
  - E.g. the value of an attribute can be an account number, but cannot be a set of account numbers
- Domain is said to be atomic if all its members are atomic
- The special value *null* is a member of every domain
- The null value causes complications in the definition of many operations
  - We shall ignore the effect of null values in our main presentation and consider their effect later

# Relation Schema

- Formally, given domains  $D_1, D_2, \dots, D_n$  a **relation**  $r$  is a subset of

$$D_1 \times D_2 \times \dots \times D_n$$

Thus, a relation is a set of  $n$ -tuples  $(a_1, a_2, \dots, a_n)$  where each  $a_i \in D_i$

- Schema of a relation consists of

- attribute definitions
  - 4 name
  - 4 type/domain
- integrity constraints

# Relation Instance

- The current values (*relation instance*) of a relation are specified by a table
- An element  $t$  of  $r$  is a *tuple*, represented by a *row* in a table
- Order of tuples is irrelevant (tuples may be stored in an arbitrary order)

The diagram illustrates a relation instance named *customer*. It is represented as a table with three columns: *customer\_name*, *customer\_street*, and *customer\_city*. The table contains four tuples (rows):

| <i>customer_name</i> | <i>customer_street</i> | <i>customer_city</i> |
|----------------------|------------------------|----------------------|
| <i>Jones</i>         | Main                   | Harrison             |
| <i>Smith</i>         | North                  | Rye                  |
| <i>Curry</i>         | North                  | Rye                  |
| <i>Lindsay</i>       | Park                   | Pittsfield           |

Annotations with arrows point to specific parts of the table:

- Three arrows point from the text "attributes (or columns)" to the column headers *customer\_name*, *customer\_street*, and *customer\_city*.
- Two arrows point from the text "tuples (or rows)" to the row containing *Jones*, Main, Harrison and the row containing *Lindsay*, Park, Pittsfield.

# Database

- A database consists of multiple relations
- Information about an enterprise is broken up into parts, with each relation storing one part of the information
- E.g.

*account* : information about accounts

*depositor* : which customer owns which account

*customer* : information about customers

# The *customer* Relation

| <i>customer_name</i> | <i>customer_street</i> | <i>customer_city</i> |
|----------------------|------------------------|----------------------|
| Adams                | Spring                 | Pittsfield           |
| Brooks               | Senator                | Brooklyn             |
| Curry                | North                  | Rye                  |
| Glenn                | Sand Hill              | Woodside             |
| Green                | Walnut                 | Stamford             |
| Hayes                | Main                   | Harrison             |
| Johnson              | Alma                   | Palo Alto            |
| Jones                | Main                   | Harrison             |
| Lindsay              | Park                   | Pittsfield           |
| Smith                | North                  | Rye                  |
| Turner               | Putnam                 | Stamford             |
| Williams             | Nassau                 | Princeton            |

# The *depositor* Relation

| <i>customer_name</i> | <i>account_number</i> |
|----------------------|-----------------------|
| Hayes                | A-102                 |
| Johnson              | A-101                 |
| Johnson              | A-201                 |
| Jones                | A-217                 |
| Lindsay              | A-222                 |
| Smith                | A-215                 |
| Turner               | A-305                 |

# Why Split Information Across Relations?

- Storing all information as a single relation such as  
 $bank(account\_number, balance, customer\_name, ..)$   
results in
  - repetition of information
    - 4 e.g., if two customers own an account (What gets repeated?)
  - the need for null values
    - 4 e.g., to represent a customer without an account
- Normalization theory (Chapter 7) deals with how to design relational schemas

# Keys

- Let  $K \subseteq R$
- $K$  is a **superkey** of  $R$  if values for  $K$  are sufficient to identify a unique tuple of each possible relation  $r(R)$ 
  - by “possible  $r$ ” we mean a relation  $r$  that could exist in the enterprise we are modeling.
  - Example:  $\{customer\_name, customer\_street\}$  and  $\{customer\_name\}$  are both superkeys of  $Customer$ , if no two customers can possibly have the same name
- 4 In real life, an attribute such as  $customer\_id$  would be used instead of  $customer\_name$  to uniquely identify customers, but we omit it to keep our examples small, and instead assume customer names are unique.

# Keys (Cont.)

- $K$  is a **candidate key** if  $K$  is minimal  
Example:  $\{customer\_name\}$  is a candidate key for *Customer*, since it is a superkey and no subset of it is a superkey.
- **Primary key:** a candidate key chosen as the principal means of identifying tuples within a relation
  - Should choose an attribute whose value never, or very rarely, changes.
  - E.g. email address is unique, but may change

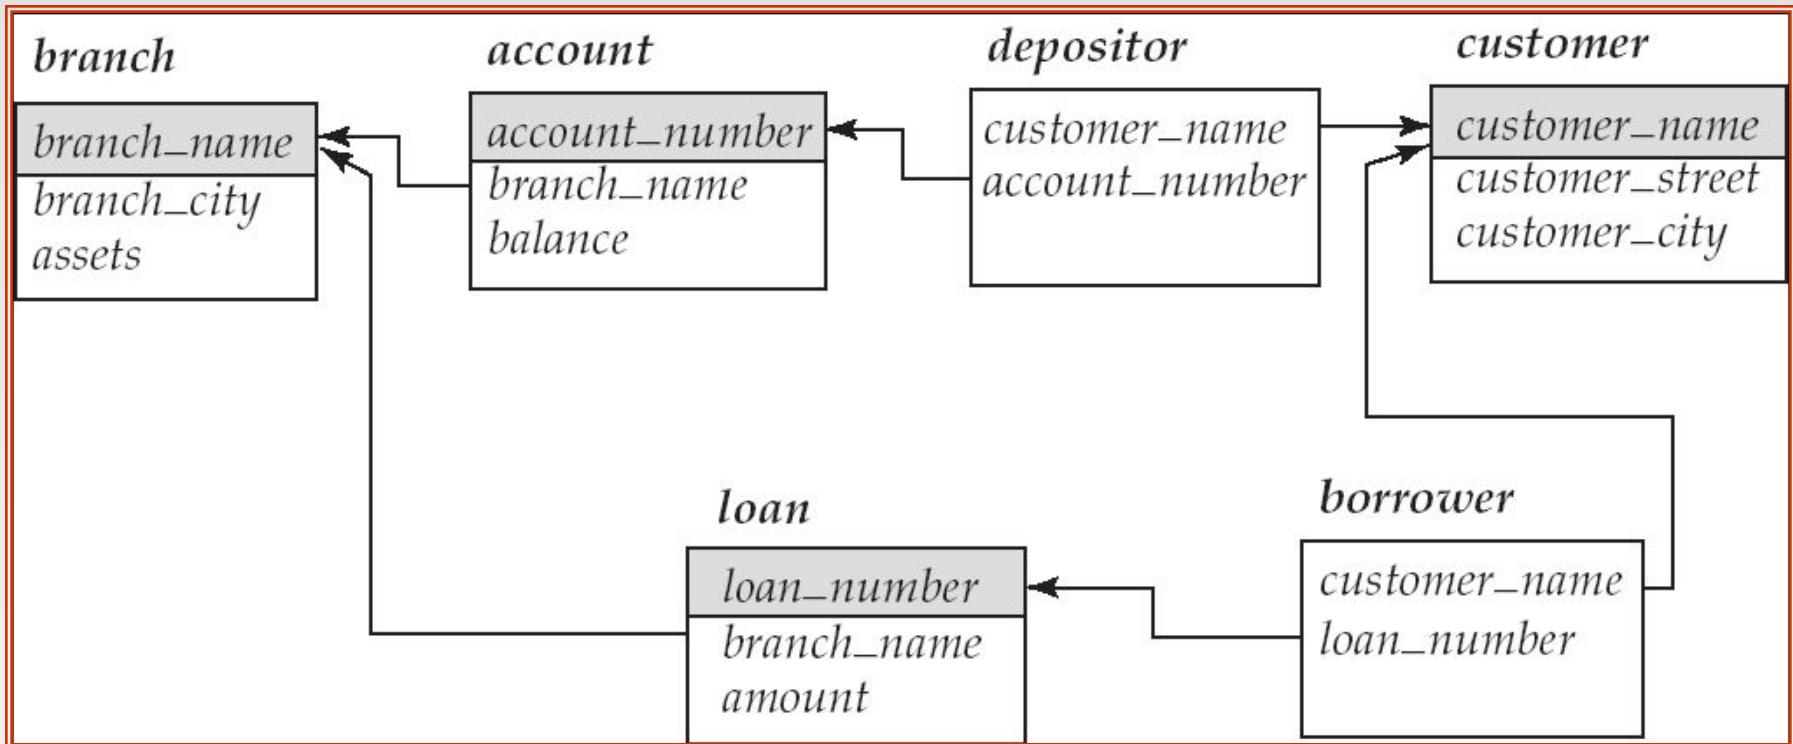

# Foreign Keys

- A relation schema may have an attribute that corresponds to the primary key of another relation. The attribute is called a **foreign key**.
  - E.g. *customer\_name* and *account\_number* attributes of *depositor* are foreign keys to *customer* and *account* respectively.
  - Only values occurring in the primary key attribute of the **referenced relation** may occur in the foreign key attribute of the **referencing relation**.

# Schema Diagram

# Query Languages

- Language in which user requests information from the database.
- Categories of languages
  - Procedural
  - Non-procedural, or declarative
- “Pure” languages:
  - Relational algebra
  - Tuple relational calculus
  - Domain relational calculus
- Pure languages form underlying basis of query languages that people use.

# Relational Algebra

- Procedural language
- Six basic operators
  - select:  $\sigma$
  - project:  $\Pi$
  - union:  $\cup$
  - set difference:  $-$
  - Cartesian product:  $\times$
  - rename:  $\rho$
- The operators take one or two relations as inputs and produce a new relation as a result.

# Select Operation – Example

- Relation r

| A        | B        | C  | D  |
|----------|----------|----|----|
| $\alpha$ | $\alpha$ | 1  | 7  |
| $\alpha$ | $\beta$  | 5  | 7  |
| $\beta$  | $\beta$  | 12 | 3  |
| $\beta$  | $\beta$  | 23 | 10 |

■  $\sigma_{A=B \wedge D > 5}(r)$

| A        | B        | C  | D  |
|----------|----------|----|----|
| $\alpha$ | $\alpha$ | 1  | 7  |
| $\beta$  | $\beta$  | 23 | 10 |

# Project Operation – Example

- Relation  $r$ :

|          | A  | B | C |
|----------|----|---|---|
| $\alpha$ | 10 | 1 |   |
| $\alpha$ | 20 | 1 |   |
| $\beta$  | 30 | 1 |   |
| $\beta$  | 40 | 2 |   |

$$\Pi_{A,C}(r)$$

|          | A | C |
|----------|---|---|
| $\alpha$ | I |   |
| $\alpha$ | I |   |
| $\beta$  | I |   |
| $\beta$  | 2 |   |

$$=$$

|          | A | C |
|----------|---|---|
| $\alpha$ | I |   |
| $\beta$  | I |   |
| $\beta$  | 2 |   |

# Union Operation – Example

- Relations  $r, s$ :

| $A$      | $B$ |
|----------|-----|
| $\alpha$ | 1   |
| $\alpha$ | 2   |
| $\beta$  | 1   |

$r$

| $A$      | $B$ |
|----------|-----|
| $\alpha$ | 2   |
| $\beta$  | 3   |

$s$

- $r \cup s$ :

| $A$      | $B$ |
|----------|-----|
| $\alpha$ | 1   |
| $\alpha$ | 2   |
| $\beta$  | 1   |
| $\beta$  | 3   |

# Set Difference Operation – Example

- Relations  $r, s$ :

| $A$      | $B$ |
|----------|-----|
| $\alpha$ | 1   |
| $\alpha$ | 2   |
| $\beta$  | 1   |

$r$

| $A$      | $B$ |
|----------|-----|
| $\alpha$ | 2   |
| $\beta$  | 3   |

$s$

- $r - s$ :

| $A$      | $B$ |
|----------|-----|
| $\alpha$ | 1   |
| $\beta$  | 1   |

# Cartesian-Product Operation – Example

- Relations  $r, s$ :

| A        | B |
|----------|---|
| $\alpha$ | 1 |
| $\beta$  | 2 |

$r$

| C        | D  | E |
|----------|----|---|
| $\alpha$ | 10 | a |
| $\beta$  | 10 | a |
| $\beta$  | 20 | b |
| $\gamma$ | 10 | b |

$s$

- $r \times s$ :

| A        | B | C        | D  | E |
|----------|---|----------|----|---|
| $\alpha$ | 1 | $\alpha$ | 10 | a |
| $\alpha$ | 1 | $\beta$  | 10 | a |
| $\alpha$ | 1 | $\beta$  | 20 | b |
| $\alpha$ | 1 | $\gamma$ | 10 | b |
| $\beta$  | 2 | $\alpha$ | 10 | a |
| $\beta$  | 2 | $\beta$  | 10 | a |
| $\beta$  | 2 | $\beta$  | 20 | b |
| $\beta$  | 2 | $\gamma$ | 10 | b |

# Rename Operation

- Allows us to name, and therefore to refer to, the results of relational-algebra expressions.
- Allows us to refer to a relation by more than one name.
- Example:

$$\rho_x(E)$$

returns the expression  $E$  under the name  $X$

- If a relational-algebra expression  $E$  has arity  $n$ , then

$$\rho_{x(A_1, A_2, \dots, A_n)}(E)$$

returns the result of expression  $E$  under the name  $X$ , and with the attributes renamed to  $A_1, A_2, \dots, A_n$ .

# Composition of Operations

- Can build expressions using multiple operations
- Example:  $\sigma_{A=C}(r \ x \ s)$
- $r \ x \ s$

| A        | B | C        | D  | E |
|----------|---|----------|----|---|
| $\alpha$ | 1 | $\alpha$ | 10 | a |
| $\alpha$ | 1 | $\beta$  | 10 | a |
| $\alpha$ | 1 | $\beta$  | 20 | b |
| $\alpha$ | 1 | $\gamma$ | 10 | b |
| $\beta$  | 2 | $\alpha$ | 10 | a |
| $\beta$  | 2 | $\beta$  | 10 | a |
| $\beta$  | 2 | $\beta$  | 20 | b |
| $\beta$  | 2 | $\gamma$ | 10 | b |

- $\sigma_{A=C}(r \ x \ s)$

| A        | B | C        | D  | E |
|----------|---|----------|----|---|
| $\alpha$ | 1 | $\alpha$ | 10 | a |
| $\beta$  | 2 | $\beta$  | 10 | a |
| $\beta$  | 2 | $\beta$  | 20 | b |

# Banking Example

*branch (branch\_name, branch\_city, assets)*

*customer (customer\_name, customer\_street, customer\_city)*

*account (account\_number, branch\_name, balance)*

*loan (loan\_number, branch\_name, amount)*

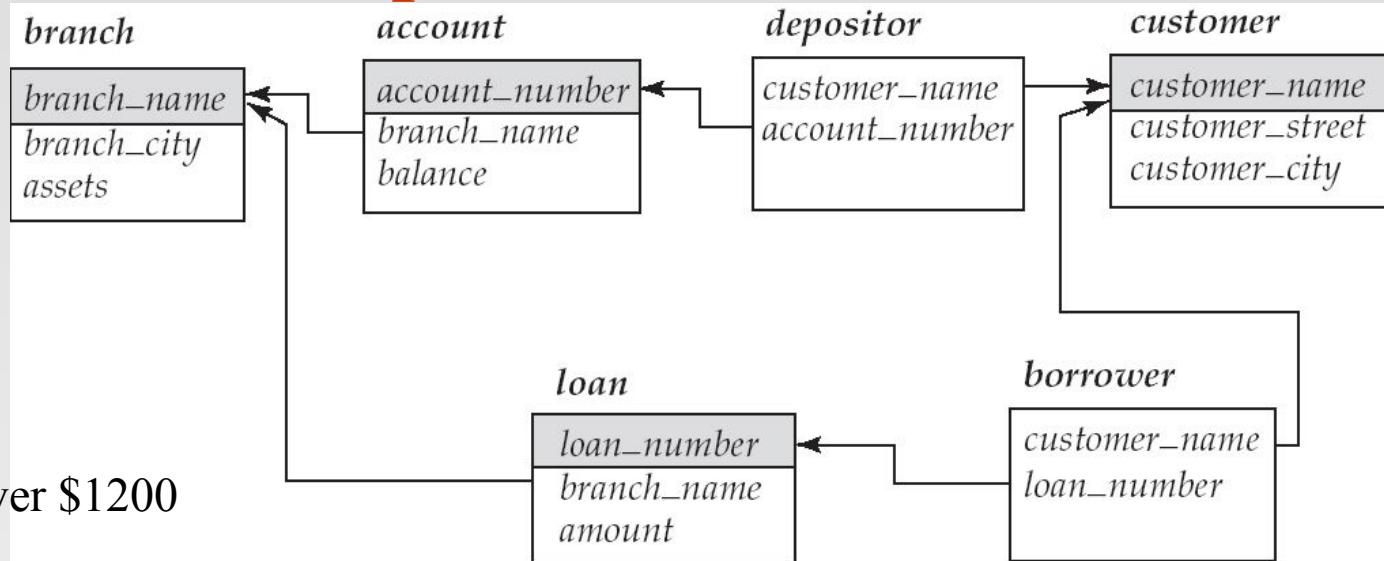

*depositor (customer\_name, account\_number)*

*borrower (customer\_name, loan\_number)*

# Example Queries

- Find all loans of over \$1200

$$\sigma_{amount > 1200} (loan)$$

- Find the loan number for each loan of an amount greater than \$1200

$$\Pi_{loan\_number} (\sigma_{amount > 1200} (loan))$$

- Find the names of all customers who have a loan, an account, or both, from the bank

$$\Pi_{customer\_name} (borrower) \cup \Pi_{customer\_name} (depositor)$$

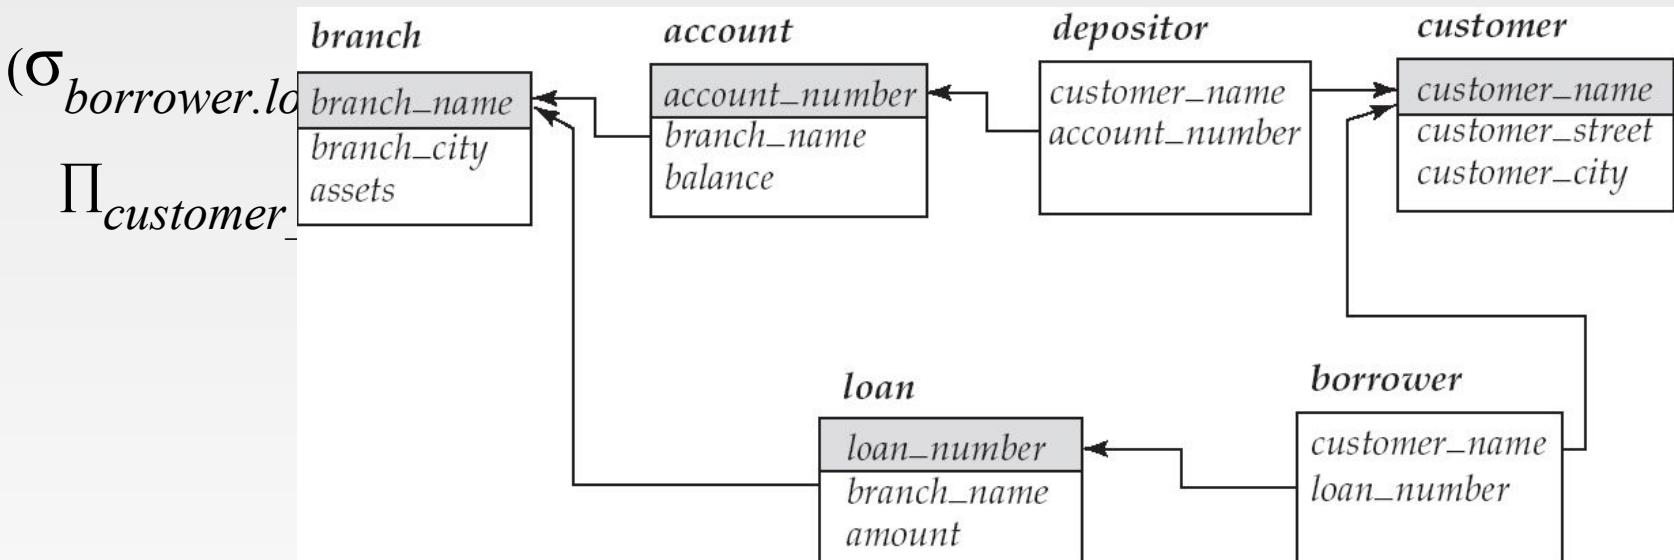

# Example Queries

- Find the names of all customers who have a loan at the Perryridge branch.

$$\prod_{customer\_name} (\sigma_{branch\_name = "Perryridge"})$$
$$(\sigma_{borrower.loan\_number = loan.loan\_number}(borrower \times loan))$$

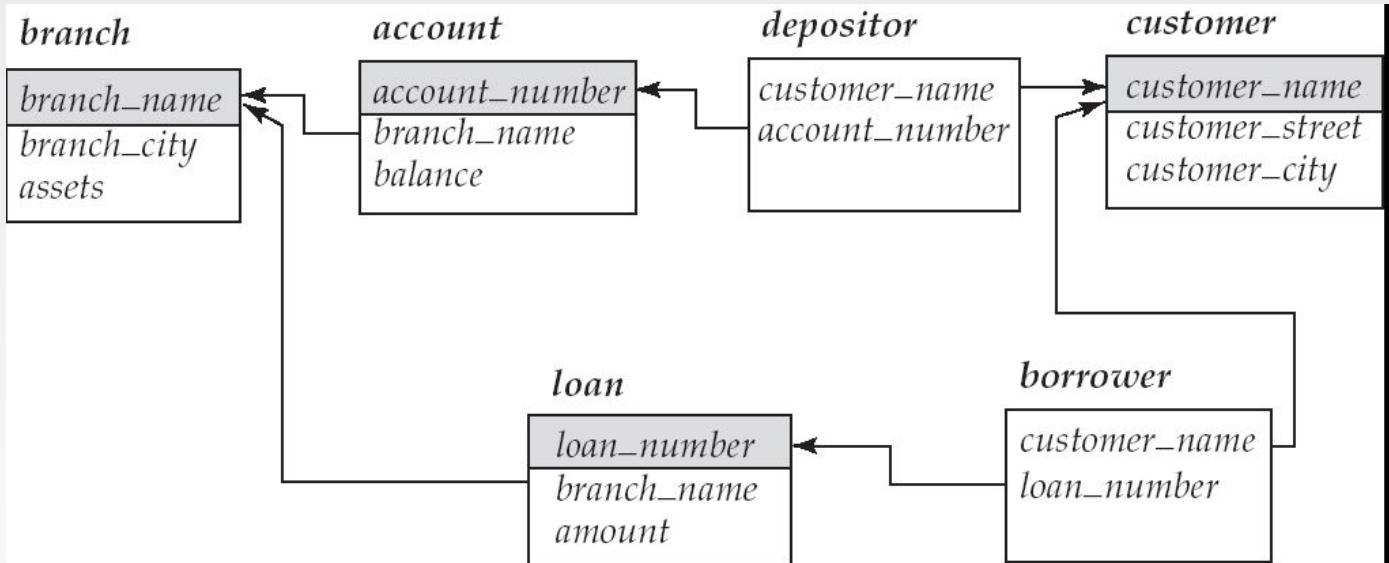

- Find the names of all customers who have a loan at the Perryridge branch but do not have an account at any branch of the bank.

$$\prod_{customer\_name} (\sigma_{branch\_name = "Perryridge"})$$

# Example Queries

- Find the names of all customers who have a loan at the Perryridge branch.
  - $\prod_{\text{customer\_name}} (\sigma_{\text{branch\_name} = \text{"Perryridge"} } ( \sigma_{\text{borrower.loan\_number} = \text{loan.loan\_number}} (\text{borrower} \times \text{loan})))$
  - $\prod_{\text{customer\_name}} (\sigma_{\text{loan.loan\_number} = \text{borrower.loan\_number}} ( \sigma_{\text{branch\_name} = \text{"Perryridge"} } (\text{loan}) \times \text{borrower}))$

# Additional Operations

- Additional Operations
  - Set intersection
  - Natural join
  - Aggregation
  - Outer Join
  - Division
- All above, other than aggregation, can be expressed using basic operations we have seen earlier

# Set-Intersection Operation – Example

- Relation  $r, s$ :

| A        | B |
|----------|---|
| $\alpha$ | 1 |
| $\alpha$ | 2 |
| $\beta$  | 1 |

$r$

| A        | B |
|----------|---|
| $\alpha$ | 2 |
| $\beta$  | 3 |

$s$

- $r \cap s$

| A        | B |
|----------|---|
| $\alpha$ | 2 |

# Natural Join Operation – Example

- Relations r, s:

| A        | B | C        | D |
|----------|---|----------|---|
| $\alpha$ | 1 | $\alpha$ | a |
| $\beta$  | 2 | $\gamma$ | a |
| $\gamma$ | 4 | $\beta$  | b |
| $\alpha$ | 1 | $\gamma$ | a |
| $\delta$ | 2 | $\beta$  | b |

r

| B | D | E        |
|---|---|----------|
| 1 | a | $\alpha$ |
| 3 | a | $\beta$  |
| 1 | a | $\gamma$ |
| 2 | b | $\delta$ |
| 3 | b | $\infty$ |

s

- $r \bowtie s$

| A        | B | C        | D | E        |
|----------|---|----------|---|----------|
| $\alpha$ | 1 | $\alpha$ | a | $\alpha$ |
| $\alpha$ | 1 | $\alpha$ | a | $\gamma$ |
| $\alpha$ | 1 | $\gamma$ | a | $\alpha$ |
| $\alpha$ | 1 | $\gamma$ | a | $\gamma$ |
| $\delta$ | 2 | $\beta$  | b | $\delta$ |

# Natural-Join Operation

- Notation:  $r \bowtie s$
- Let  $r$  and  $s$  be relations on schemas  $R$  and  $S$  respectively.  
Then,  $r \bowtie s$  is a relation on schema  $R \cup S$  obtained as follows:
  - Consider each pair of tuples  $t_r$  from  $r$  and  $t_s$  from  $s$ .
  - If  $t_r$  and  $t_s$  have the same value on each of the attributes in  $R \cap S$ , add a tuple  $t$  to the result, where
    - $t$  has the same value as  $t_r$  on  $r$
    - $t$  has the same value as  $t_s$  on  $s$
- Example:
  - $R = (A, B, C, D)$
  - $S = (E, \underset{\bowtie}{B}, D)$
  - Result schema =  $(A, B, C, D, E)$
  - $r \bowtie s$  is defined as:

## EXAMPLES OF ALGEBRA QUERIES

Consider instances S3 of sailors, R2 of Reserves and B1 of boats.

| <i>sid</i> | <i>sname</i> | <i>rating</i> | <i>age</i> |
|------------|--------------|---------------|------------|
| 22         | Dustin       | 7             | 45.0       |
| 29         | Brutus       | 1             | 33.0       |
| 31         | Lubber       | 8             | 55.5       |
| 32         | Andy         | 8             | 25.5       |
| 58         | Rusty        | 10            | 35.0       |
| 64         | Horatio      | 7             | 35.0       |
| 71         | Zorba        | 10            | 16.0       |
| 74         | Horatio      | 9             | 35.0       |
| 85         | Art          | 3             | 25.5       |
| 95         | Bob          | 3             | 63.5       |

**Figure 4.15** An Instance S3 of Sailors

| <i>sid</i> | <i>bid</i> | <i>day</i> |
|------------|------------|------------|
| 22         | 101        | 10/10/98   |
| 22         | 102        | 10/10/98   |
| 22         | 103        | 10/8/98    |
| 22         | 104        | 10/7/98    |
| 31         | 102        | 11/10/98   |
| 31         | 103        | 11/6/98    |
| 31         | 104        | 11/12/98   |
| 64         | 101        | 9/5/98     |
| 64         | 102        | 9/8/98     |
| 74         | 103        | 9/8/98     |

**Figure 4.16** An Instance R2 of Reserves

| <i>bid</i> | <i>bname</i> | <i>color</i> |
|------------|--------------|--------------|
| 101        | Interlake    | blue         |
| 102        | Interlake    | red          |
| 103        | Clipper      | green        |
| 104        | Marine       | red          |

**Figure 4.17** An Instance B1 of Boats

# QUERY Q1

Given the relational instances:

| <i>sid</i> | <i>sname</i> | <i>rating</i> | <i>age</i> |
|------------|--------------|---------------|------------|
| 22         | Dustin       | 7             | 45.0       |
| 29         | Brutus       | 1             | 33.0       |
| 31         | Lubber       | 8             | 55.5       |
| 32         | Andy         | 8             | 25.5       |
| 58         | Rusty        | 10            | 35.0       |
| 64         | Horatio      | 7             | 35.0       |
| 71         | Zorba        | 10            | 16.0       |
| 74         | Horatio      | 9             | 35.0       |
| 85         | Art          | 3             | 25.5       |
| 95         | Bob          | 3             | 63.5       |

**Figure 4.15** An Instance *S3* of Sailors

| <i>sid</i> | <i>bid</i> | <i>day</i> |
|------------|------------|------------|
| 22         | 101        | 10/10/98   |
| 22         | 102        | 10/10/98   |
| 22         | 103        | 10/8/98    |
| 22         | 104        | 10/7/98    |
| 31         | 102        | 11/10/98   |
| 31         | 103        | 11/6/98    |
| 31         | 104        | 11/12/98   |
| 64         | 101        | 9/5/98     |
| 64         | 102        | 9/8/98     |
| 74         | 103        | 9/8/98     |

**Figure 4.16** An Instance *R2* of Reserves

**(Q1) Find the names of sailors who have reserved boat 103**

$$\pi_{sname}((\sigma_{bid=103} Reserves) \bowtie Sailors)$$

The answer is thus the following relational instance

{<Dustin>, <Lubber>, <Horatio>}

## QUERY Q1 (cont'd)

There are of course several ways to express Q1 in relational algebra.

Here is another:

$$\pi_{sname}(\sigma_{bid=103}(\text{Reserves} \bowtie \text{Sailors}))$$

Which of these expressions should we use?

That is a question of optimization. Indeed, when we describe how to state queries in SQL, we can leave it to the optimizer in the DBMS to select the nest approach.

## QUERY Q2

*(Q2) Find the names of sailors who have reserved a red boat.*

| <i>sid</i> | <i>sname</i> | <i>rating</i> | <i>age</i> | <i>bid</i> | <i>day</i> |
|------------|--------------|---------------|------------|------------|------------|
| 22         | Dustin       | 7             | 45.0       | 22         | 101        |

$\pi_{\text{sname}}(\text{Tempboats} \bowtie \text{Reserves} \bowtie \text{Sailors})$

## QUERY Q6

(Q6) Find the names of Sailors who have reserved a red and a green boat.

It seems tempting to use the expression used in Q5, replacing simply  $\cup$  by  $\cap$ . However, this won't work, for such an expression is requesting the names of sailors who have requested a boat that is both red and green! The correct expression is as follows:

$$\rho(Tempred, \pi_{sid}((\sigma_{color='red'}Boats) \bowtie Reserves))$$
$$\rho(Tempgreen, \pi_{sid}((\sigma_{color='green'}Boats) \bowtie Reserves))$$
$$\pi_{sname} ((Tempred \cap Tempgreen) \bowtie Sailors)$$

# QUERY Q7

# Bank Example Queries

- Find the largest account balance
  - Strategy:
    - 4 Find those balances that are *not* the largest
      - Rename *account* relation as *d* so that we can compare each account balance with all others
    - 4 Use set difference to find those account balances that were *not* found in the earlier step.
  - The query is:

$$\begin{aligned} & \prod_{balance}(account) - \prod_{account.balance} \\ & (\sigma_{account.balance < d.balance} (account \times \rho_d(account))) \end{aligned}$$

| <i>account</i>        |
|-----------------------|
| <i>account_number</i> |
| <i>branch_name</i>    |
| <i>balance</i>        |

# Aggregate Functions and Operations

- **Aggregation function** takes a collection of values and returns a single value as a result.

**avg**: average value

**min**: minimum value

**max**: maximum value

**sum**: sum of values

**count**: number of values

- **Aggregate operation** in relational algebra

$$g_{G_1, G_2, \dots, G_n} F_1(A_1), F_2(A_2, \dots, A_n) (E)$$

$E$  is any relational-algebra expression

- $G_1, G_2, \dots, G_n$  is a list of attributes on which to group (can be empty)
- Each  $F_i$  is an aggregate function
- Each  $A_i$  is an attribute name

# Aggregate Operation – Example

- Relation  $r$ :

| $A$      | $B$      | $C$ |
|----------|----------|-----|
| $\alpha$ | $\alpha$ | 7   |
| $\alpha$ | $\beta$  | 7   |
| $\beta$  | $\beta$  | 3   |
| $\beta$  | $\beta$  | 10  |

- $g_{\text{sum}(c)}(r)$

|                 |
|-----------------|
| $\text{sum}(c)$ |
| 27              |

- Question: Which aggregate operations cannot be expressed using basic relational operations?

# Aggregate Operation – Example

- Relation *account* grouped by *branch-name*:

| <i>branch_name</i> | <i>account_number</i> | <i>balance</i> |
|--------------------|-----------------------|----------------|
| Perryridge         | A-102                 | 400            |
| Perryridge         | A-201                 | 900            |
| Brighton           | A-217                 | 750            |
| Brighton           | A-215                 | 750            |
| Redwood            | A-222                 | 700            |

*branch\_name* g **sum(balance)** (*account*)

| <i>branch_name</i> | <b>sum(balance)</b> |
|--------------------|---------------------|
| Perryridge         | 1300                |
| Brighton           | 1500                |
| Redwood            | 700                 |

# Aggregate Functions (Cont.)

- Result of aggregation does not have a name
  - Can use rename operation to give it a name
  - For convenience, we permit renaming as part of aggregate operation

*branch\_name*  $\text{g sum(balance) as sum_balance}$  (*account*)

# Outer Join

- An extension of the join operation that avoids loss of information.
- Computes the join and then adds tuples from one relation that does not match tuples in the other relation to the result of the join.
- Uses *null* values:
  - *null* signifies that the value is unknown or does not exist
  - All comparisons involving *null* are (roughly speaking) **false** by definition.
    - 4 We shall study precise meaning of comparisons with nulls later

# Outer Join – Example

- Relation *loan*

| <i>loan_number</i> | <i>branch_name</i> | <i>amount</i> |
|--------------------|--------------------|---------------|
| L-170              | Downtown           | 3000          |
| L-230              | Redwood            | 4000          |
| L-260              | Perryridge         | 1700          |

- Relation *borrower*

| <i>customer_name</i> | <i>loan_number</i> |
|----------------------|--------------------|
| Jones                | L-170              |
| Smith                | L-230              |
| Hayes                | L-155              |

# Outer Join – Example

- Join

$loan \bowtie borrower$

| <i>loan_number</i> | <i>branch_name</i> | <i>amount</i> | <i>customer_name</i> |
|--------------------|--------------------|---------------|----------------------|
| L-170              | Downtown           | 3000          | Jones                |
| L-230              | Redwood            | 4000          | Smith                |

- Left Outer Join

$loan \text{ } \bowtie \text{ } \bowtie \text{ } borrower$

| <i>loan_number</i> | <i>branch_name</i> | <i>amount</i> | <i>customer_name</i> |
|--------------------|--------------------|---------------|----------------------|
| L-170              | Downtown           | 3000          | Jones                |
| L-230              | Redwood            | 4000          | Smith                |
| L-260              | Perryridge         | 1700          | <i>null</i>          |

# Outer Join – Example

- Right Outer Join

$loan \bowtie[borrower]$

| <i>loan_number</i> | <i>branch_name</i> | <i>amount</i> | <i>customer_name</i> |
|--------------------|--------------------|---------------|----------------------|
| L-170              | Downtown           | 3000          | Jones                |
| L-230              | Redwood            | 4000          | Smith                |
| L-155              | <i>null</i>        | <i>null</i>   | Hayes                |

- Full Outer Join

$loan \bowtie[borrower]$

| <i>loan_number</i> | <i>branch_name</i> | <i>amount</i> | <i>customer_name</i> |
|--------------------|--------------------|---------------|----------------------|
| L-170              | Downtown           | 3000          | Jones                |
| L-230              | Redwood            | 4000          | Smith                |
| L-260              | Perryridge         | 1700          | <i>null</i>          |
| L-155              | <i>null</i>        | <i>null</i>   | Hayes                |

- Question:** can outerjoins be expressed using basic relational algebra operations

# Null Values

- It is possible for tuples to have a null value, denoted by *null*, for some of their attributes
- *null* signifies an unknown value or that a value does not exist.
- The result of any arithmetic expression involving *null* is *null*.
- Aggregate functions simply ignore null values (as in SQL)
- For duplicate elimination and grouping, null is treated like any other value, and two nulls are assumed to be the same (as in SQL)

# Null Values

- Comparisons with null values return the special truth value: *unknown*
  - If *false* was used instead of *unknown*, then  $\text{not } (A < 5)$  would not be equivalent to  $A \geq 5$
- Three-valued logic using the truth value *unknown*:
  - OR:  $(\text{unknown} \text{ or } \text{true}) = \text{true}$ ,  
 $(\text{unknown} \text{ or } \text{false}) = \text{unknown}$   
 $(\text{unknown} \text{ or } \text{unknown}) = \text{unknown}$
  - AND:  $(\text{true} \text{ and } \text{unknown}) = \text{unknown}$ ,  
 $(\text{false} \text{ and } \text{unknown}) = \text{false}$ ,  
 $(\text{unknown} \text{ and } \text{unknown}) = \text{unknown}$
  - NOT:  $(\text{not } \text{unknown}) = \text{unknown}$
  - In SQL “*P is unknown*” evaluates to true if predicate *P* evaluates to *unknown*
- Result of select predicate is treated as *false* if it evaluates to *unknown*

# Division Operation

$r$

- Notation:  $r \div s$
- Suited to queries that include the phrase “for all”.
- Let  $r$  and  $s$  be relations on schemas  $R$  and  $S$  respectively where
  - $R = (A_1, \dots, A_m, B_1, \dots, B_n)$
  - $S = (B_1, \dots, B_n)$

The result of  $r \div s$  is a relation on schema

$$R - S = (A_1, \dots, A_m)$$

$$r \div s = \{ t \mid t \in \prod_{R-S}(r) \wedge \forall u \in s (tu \in r) \}$$

Where  $tu$  means the concatenation of tuples  $t$  and  $u$  to produce a single tuple

# Division Operation – Example

- Relations  $r, s$ :

| $A$      | $B$ |
|----------|-----|
| $\alpha$ | 1   |
| $\alpha$ | 2   |
| $\alpha$ | 3   |
| $\beta$  | 1   |
| $\gamma$ | 1   |
| $\delta$ | 1   |
| $\delta$ | 3   |
| $\delta$ | 4   |
| $\in$    | 6   |
| $\in$    | 1   |
| $\beta$  | 2   |

| $B$ |
|-----|
| 1   |
| 2   |

$s$

- $r \div s$ :

| $A$      |
|----------|
| $\alpha$ |
| $\beta$  |

$r$

# Another Division Example

- Relations  $r, s$ :

| $A$      | $B$ | $C$      | $D$ | $E$ |
|----------|-----|----------|-----|-----|
| $\alpha$ | a   | $\alpha$ | a   | 1   |
| $\alpha$ | a   | $\gamma$ | a   | 1   |
| $\alpha$ | a   | $\gamma$ | b   | 1   |
| $\beta$  | a   | $\gamma$ | a   | 1   |
| $\beta$  | a   | $\gamma$ | b   | 3   |
| $\gamma$ | a   | $\gamma$ | a   | 1   |
| $\gamma$ | a   | $\gamma$ | b   | 1   |
| $\gamma$ | a   | $\beta$  | b   | 1   |

$r$

| $D$ | $E$ |
|-----|-----|
| a   | 1   |
| b   | 1   |

$s$

- $r \div s$ :

| $A$      | $B$ | $C$      |
|----------|-----|----------|
| $\alpha$ | a   | $\gamma$ |
| $\gamma$ | a   | $\gamma$ |

# Division Operation (Cont.)

- Property
  - Let  $q = r \div s$
  - Then  $q$  is the largest relation satisfying  $q \times s \subseteq r$
- Definition in terms of the basic algebra operation  
Let  $r(R)$  and  $s(S)$  be relations, and let  $S \subseteq R$

$$r \div s = \Pi_{R-S}(r) - \Pi_{R-S}((\Pi_{R-S}(r) \times s) - \Pi_{R-S,S}(r))$$

To see why

- $\Pi_{R-S,S}(r)$  simply reorders attributes of  $r$
- $\Pi_{R-S}(\Pi_{R-S}(r) \times s) - \Pi_{R-S,S}(r)$  gives those tuples  $t$  in  $\Pi_{R-S}(r)$  such that for some tuple  $u \in s$ ,  $tu \notin r$ .

# Bank Example Queries

- Find the names of all customers who have a loan and an account at bank.

$$\Pi_{customer\_name} (borrower) \cap \Pi_{customer\_name} (depositor)$$

- Find the name of all customers who have a loan at the bank and the loan amount

$$\Pi_{customer\_name, loan\_number, amount} (borrower \quad \text{loan})$$

# Bank Example Queries

- Find all customers who have an account from at least the “Downtown” and the Uptown” branches.
  - Query 1

$$\begin{aligned} & \prod_{customer\_name} (\sigma_{branch\_name = "Downtown"}(depositor \quad account)) \cap \\ & \prod_{customer\_name} (\sigma_{branch\_name = "Uptown"}(depositor \quad account)) \end{aligned}$$

- Query 2

$$\begin{aligned} & \prod_{customer\_name, branch\_name} (depositor \quad account) \\ & \div \rho_{temp(branch\_name)}(\{("Downtown"), ("Uptown")\}) \end{aligned}$$

Note that Query 2 uses a constant relation.

# Bank Example Queries

- Find all customers who have an account at all branches located in Brooklyn city.

$$\begin{aligned} & \prod_{customer\_name, branch\_name} (depositor \quad account) \\ & \div \prod_{branch\_name} (\sigma_{branch\_city = "Brooklyn"} (branch)) \end{aligned}$$

# End of Chapter 2

**Database System Concepts, 5<sup>th</sup> Ed.**

©Silberschatz, Korth and Sudarshan  
See [www.db-book.com](http://www.db-book.com) for conditions on re-use

# Formal Definition

- A basic expression in the relational algebra consists of either one of the following:
  - A relation in the database
  - A constant relation
- Let  $E_1$  and  $E_2$  be relational-algebra expressions; the following are all relational-algebra expressions:
  - $E_1 \cup E_2$
  - $E_1 - E_2$
  - $E_1 \times E_2$
  - $\sigma_p(E_1)$ ,  $P$  is a predicate on attributes in  $E_1$
  - $\Pi_s(E_1)$ ,  $S$  is a list consisting of some of the attributes in  $E_1$
  - $\rho_x(E_1)$ ,  $x$  is the new name for the result of  $E_1$

# Select Operation

- Notation:  $\sigma_p(r)$
- $p$  is called the **selection predicate**
- Defined as:

$$\sigma_p(r) = \{t \mid t \in r \text{ and } p(t)\}$$

Where  $p$  is a formula in propositional calculus consisting of **terms** connected by :  $\wedge$  (**and**),  $\vee$  (**or**),  $\neg$  (**not**)

Each **term** is one of:

$\langle \text{attribute} \rangle op \quad \langle \text{attribute} \rangle \text{ or } \langle \text{constant} \rangle$

where  $op$  is one of:  $=, \neq, >, \geq, <, \leq$

- Example of selection:

$$\sigma_{branch\_name = "Perryridge"}(account)$$

# Project Operation

- Notation:

$$\prod_{A_1, A_2, \dots, A_k} (r)$$

where  $A_1, A_2$  are attribute names and  $r$  is a relation name.

- The result is defined as the relation of  $k$  columns obtained by erasing the columns that are not listed
- Duplicate rows removed from result, since relations are sets
- Example: To eliminate the *branch\_name* attribute of *account*

$$\prod_{\text{account\_number}, \text{balance}} (\text{account})$$

# Union Operation

- Notation:  $r \cup s$
- Defined as:
$$r \cup s = \{t \mid t \in r \text{ or } t \in s\}$$
- For  $r \cup s$  to be valid.
  - $r, s$  must have the *same arity* (same number of attributes)
  - The attribute domains must be **compatible** (example: 2<sup>nd</sup> column of  $r$  deals with the same type of values as does the 2<sup>nd</sup> column of  $s$ )
- Example: to find all customers with either an account or a loan

$$\prod_{customer\_name} (depositor) \cup \prod_{customer\_name} (borrower)$$

# Set Difference Operation

- Notation  $r - s$
- Defined as:
$$r - s = \{t \mid t \in r \text{ and } t \notin s\}$$
- Set differences must be taken between **compatible** relations.
  - $r$  and  $s$  must have the **same** arity
  - attribute domains of  $r$  and  $s$  must be compatible

# Cartesian-Product Operation

- Notation  $r \times s$
- Defined as:

$$r \times s = \{t q \mid t \in r \text{ and } q \in s\}$$

- Assume that attributes of  $r(R)$  and  $s(S)$  are disjoint. (That is,  $R \cap S = \emptyset$ ).
- If attributes of  $r$  and  $s$  are not disjoint, then renaming must be used.

# Set-Intersection Operation

- Notation:  $r \cap s$
- Defined as:
- $r \cap s = \{ t \mid t \in r \text{ and } t \in s \}$
- Assume:
  - $r, s$  have the *same arity*
  - attributes of  $r$  and  $s$  are compatible
- Note:  $r \cap s = r - (r - s)$

# Assignment Operation

- The assignment operation ( $\leftarrow$ ) provides a convenient way to express complex queries.
  - Write query as a sequential program consisting of
    - 4 a series of assignments
    - 4 followed by an expression whose value is displayed as a result of the query.
  - Assignment must always be made to a temporary relation variable.
- Example: Write  $r \div s$  as

$$temp1 \leftarrow \prod_{R-S}(r)$$
$$temp2 \leftarrow \prod_{R-S}((temp1 \times s) - \prod_{R-S,S}(r))$$
$$result = temp1 - temp2$$

- The result to the right of the  $\leftarrow$  is assigned to the relation variable on the left of the  $\leftarrow$ .
- May use variable in subsequent expressions.

# Extended Relational-Algebra-Operations

- Generalized Projection
- Aggregate Functions
- Outer Join

# Generalized Projection

- Extends the projection operation by allowing arithmetic functions to be used in the projection list.

$$\prod_{F_1, F_2, \dots, F_n}(E)$$

- $E$  is any relational-algebra expression
- Each of  $F_1, F_2, \dots, F_n$  are arithmetic expressions involving constants and attributes in the schema of  $E$ .
- Given relation  $credit\_info(customer\_name, limit, credit\_balance)$ , find how much more each person can spend:

$$\prod_{customer\_name, limit - credit\_balance}(credit\_info)$$

# Modification of the Database

- The content of the database may be modified using the following operations:
  - Deletion
  - Insertion
  - Updating
- All these operations are expressed using the assignment operator.

# Deletion

- A delete request is expressed similarly to a query, except instead of displaying tuples to the user, the selected tuples are removed from the database.
- Can delete only whole tuples; cannot delete values on only particular attributes
- A deletion is expressed in relational algebra by:

$$r \leftarrow r - E$$

where  $r$  is a relation and  $E$  is a relational algebra query.

# Deletion Examples

- Delete all account records in the Perryridge branch.

$$account \leftarrow account - \sigma_{branch\_name = "Perryridge"}(account)$$

- Delete all loan records with amount in the range of 0 to 50

$$loan \leftarrow loan - \sigma_{amount \geq 0 \text{ and } amount \leq 50}(loan)$$

- Delete all accounts at branches located in Needham.

$$r_1 \leftarrow \sigma_{branch\_city = "Needham"}(account \bowtie branch)$$
$$r_2 \leftarrow \prod_{account\_number, branch\_name, balance} (r_1)$$
$$r_3 \leftarrow \prod_{customer\_name, account\_number} (r_2 \bowtie depositor)$$
$$account \leftarrow account - r_2$$
$$depositor \leftarrow depositor - r_3$$

# Insertion

- To insert data into a relation, we either:
  - specify a tuple to be inserted
  - write a query whose result is a set of tuples to be inserted
- in relational algebra, an insertion is expressed by:

$$r \leftarrow r \cup E$$

where  $r$  is a relation and  $E$  is a relational algebra expression.

- The insertion of a single tuple is expressed by letting  $E$  be a constant relation containing one tuple.

# Insertion Examples

- Insert information in the database specifying that Smith has \$1200 in account A-973 at the Perryridge branch.

$$account \leftarrow account \cup \{("A-973", "Perryridge", 1200)\}$$
$$depositor \leftarrow depositor \cup \{("Smith", "A-973")\}$$

- Provide as a gift for all loan customers in the Perryridge branch, a \$200 savings account. Let the loan number serve as the account number for the new savings account.

$$r_1 \leftarrow (\sigma_{branch\_name = "Perryridge"} (borrower \bowtie loan))$$
$$account \leftarrow account \cup \prod_{loan\_number, branch\_name, 200} (r_1)$$
$$depositor \leftarrow depositor \cup \prod_{customer\_name, loan\_number} (r_1)$$

# Updating

- A mechanism to change a value in a tuple without changing *all* values in the tuple
- Use the generalized projection operator to do this task

$$r \leftarrow \prod_{F_1, F_2, \dots, F_l} (r)$$

- Each  $F_i$  is either
  - the  $I^{\text{th}}$  attribute of  $r$ , if the  $I^{\text{th}}$  attribute is not updated, or,
  - if the attribute is to be updated  $F_i$  is an expression, involving only constants and the attributes of  $r$ , which gives the new value for the attribute

# Update Examples

- Make interest payments by increasing all balances by 5 percent.

$$account \leftarrow \prod_{account\_number, branch\_name, balance} (account) * 1.05$$

- Pay all accounts with balances over \$10,000 6 percent interest  
and pay all others 5 percent

$$\begin{aligned} account \leftarrow & \prod_{account\_number, branch\_name, balance} (account) * 1.06 \quad (\sigma_{BAL > 10000}(account)) \\ \cup & \prod_{account\_number, branch\_name, balance} (account) * 1.05 \quad (\sigma_{BAL \leq 10000}(account)) \end{aligned}$$
